AirSpiral™ for less condensate*
We've all seen it happen before. When warm, humid gas touches anything even a fraction of a degree colder than itself, it cools and generates condensate. We see it often in conventional breathing tubes made of thin, dense plastic: their surfaces are easily cooled by the outside air, resulting in unpleasant “rain-out”.

The new AirSpiral™ tube for AIRVO 2 utilizes an advanced two-spiral design to help protect against condensate:

- **The heating spiral** contains heater wire to warm the breathing gas inside the tube.
- **The insulating spiral** uses a bubble of warmed air around the breathing gas to shield it from the outside environment.

Like a double-paned window, the inside and outside surfaces of the tube are physically separated, to reduce cooling and helps maximize the level of humidity remaining in the gas all the way to the patient.

**BENEFITS**

- **2-in-1 tube**
  - Connects with both Optiflow™ and Optiflow™ Junior interfaces
- **Integrated temperature sensor**
  - No external probes, cables or adaptors required.

**AirSpiral tube** produces up to **93% less condensate** than a previous AIRVO tube.

Less condensate may reduce interruptions to therapy.

For further information about the AirSpiral tube, including warnings and precautions, please read the user instructions.
